

Image adjustment (levels, curves, contrast etc) before and after scanning

After adjusting (ie. changing curves) the image, it has lost some information.

Test: If you now want to change the image again (ie. change levels), you can see that there is some information missing

Image before adjusting

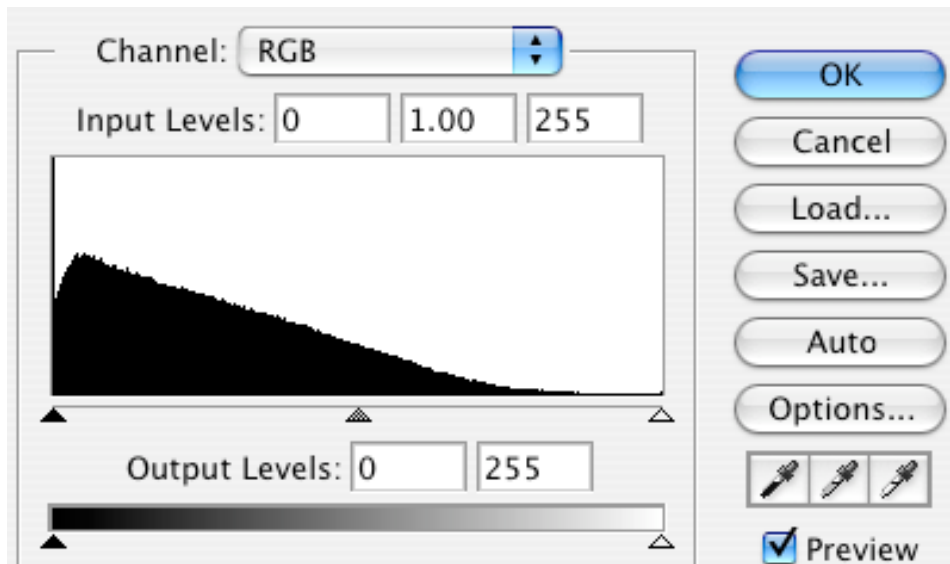

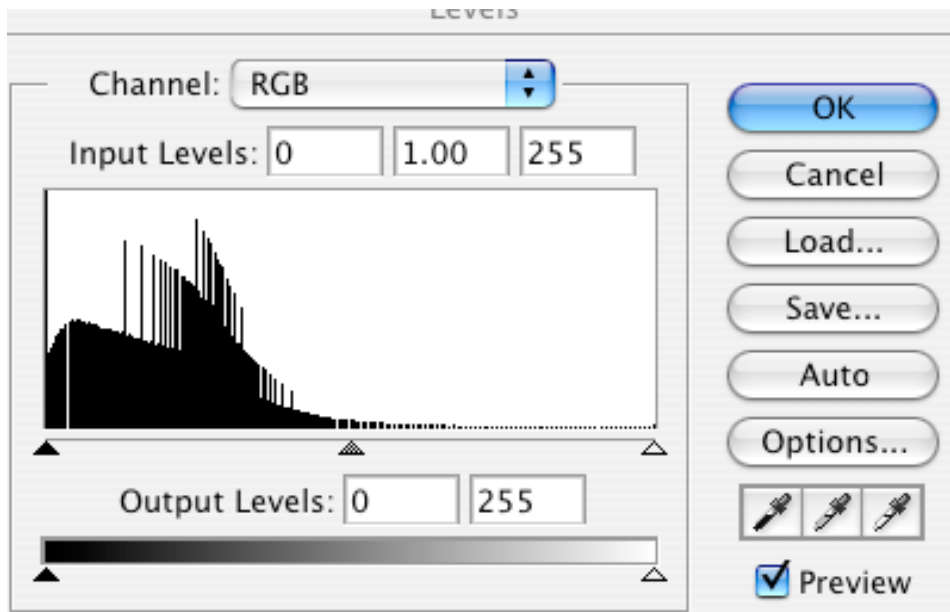

Image after adjusting

Solution:

If you adjust before scanning, you can keep the full information -> this means that at the end it remains in a better quality.

Disadvantage: Editing the image before scanning mostly does not offer a zoom tool for a better view, therefore it is maybe more difficult to get a good result than editing afterwards.
